

# Is the USDB interaction unique?

Towards shell model interactions with credible uncertainties

---

Nuclear Structure I, APS Global Physics Summit, Anaheim, CA

Tuesday March 18, 1:54 pm – 2:06 pm

**Oliver Gorton**

Nuclear Data and Theory Group

Prepared by LLNL under Contract DE-AC52-07NA27344.

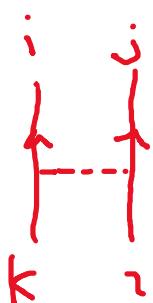

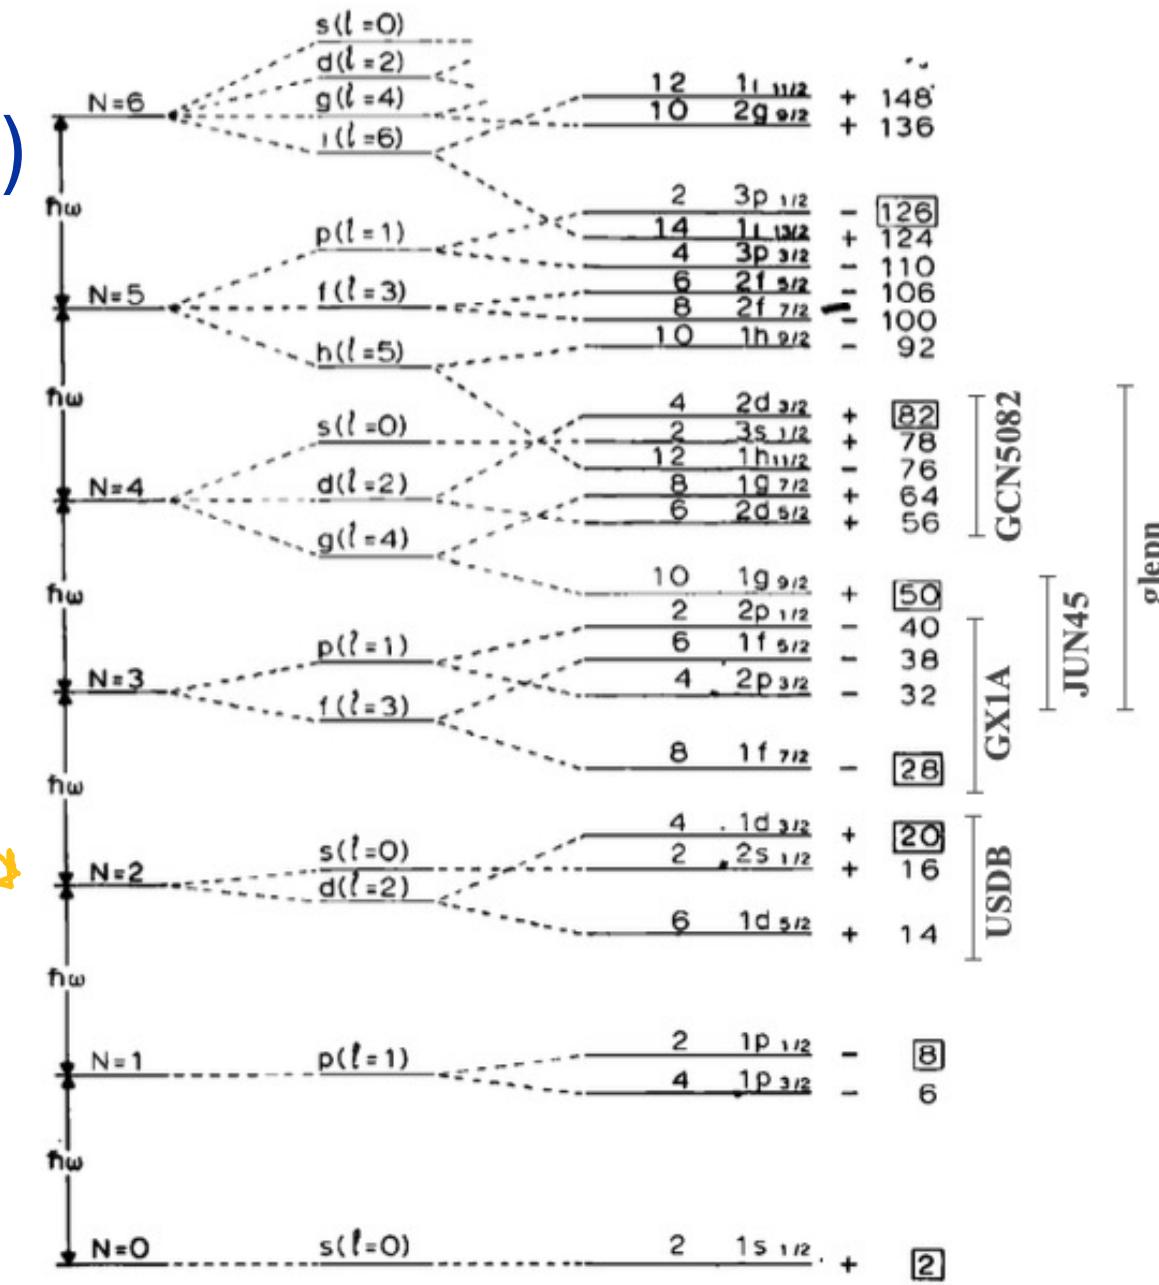

# Nuclear shell model (no core)

# of particles in these orbits:  
Mean-field energy

$$\hat{H}(\mathbf{c}) = \sum_i \epsilon_i \hat{n}_i + \sum_{i \leq j, k \leq l; JT} V_{ijkl; JT} \hat{T}_{ijkl; JT}$$

Matrix elements:  
Residual 2-body interaction

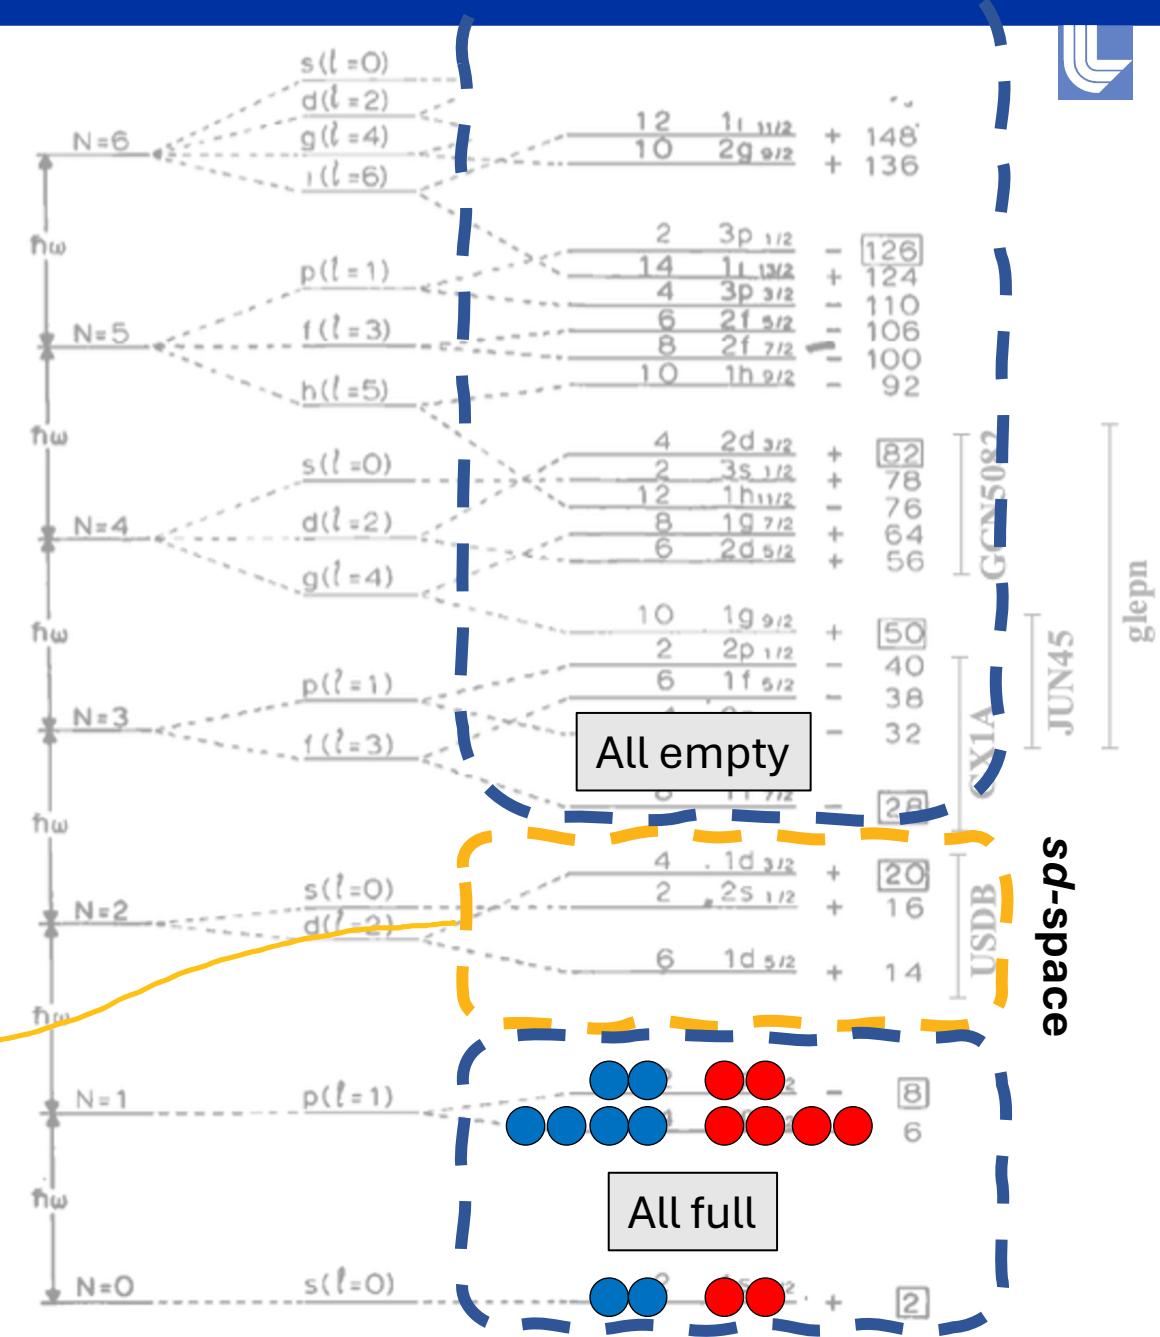

Get these from effective field theory

# Nuclear shell model (with core)

$$\hat{H}(\mathbf{c}) = \sum_i \epsilon_i \hat{n}_i + \sum_{i \leq j, k \leq l; JT} V_{ijkl; JT} \hat{T}_{ijkl; JT}$$

## Renormalized “effective interaction”

# USDB: the most famous renormalized-interaction

B. A. Brown *et al.*, PRC 74, 034315 (2006)

- 3 single-particle energies
- 66 residual two-body matrix elements
- Fit to data:

$$\min_c \chi^2 = \min_c \sum_{i=1}^{608} \left( \frac{SM_i(c) - E_i}{\sigma_i} \right)^2$$

$$\sigma_i^2 = \sigma_i^2(\text{Experiment}) + \sigma_i^2(\text{Theory})$$

a few keV  $\ll$  150 keV

- 608 energy levels
  - 77 binding energies
  - 531 excitation energies

# USDB: 130 keV is the uncertainty of the shell model

B.A.Brown et al., PRC 74, 034315 (2006)

B.A.Brown et al., PRC 74, 034315 (2006)

$$\min_c \chi^2 = \sum_{i=1}^{608} \left( \frac{SM_i(c) - E_i}{\sigma_i} \right)^2$$

608 energy levels  
 • 77 binding energies  
 • 531 excitation energies

$$\sigma_i^2 = \sigma_i^2(\text{Experiment}) + \sigma_i^2(\text{Theory})$$

a few keV << 150 keV

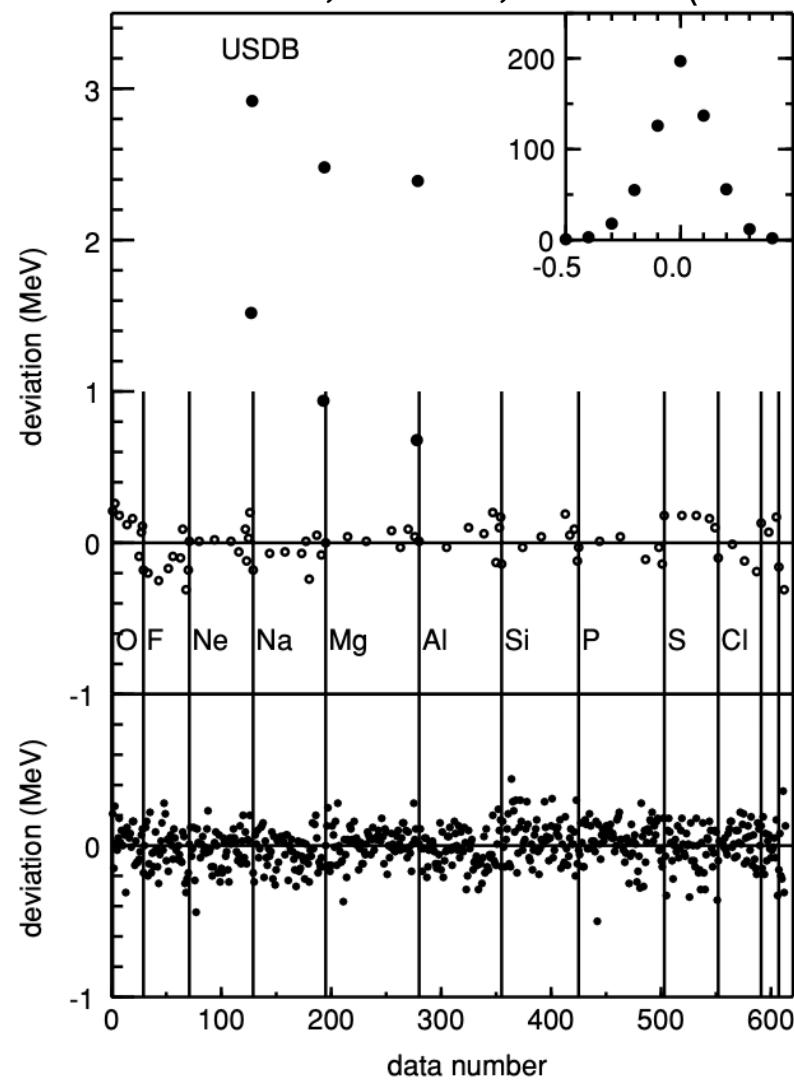

$\chi^2$ -minimization UQ analysis:

- Uncertainty set by parameter-of-fit:  $\sigma(\text{theory})$
- Analysis assumes linear approximation
- Assumes multivariate normal distribution of parameters

J.Fox et al., PRC 108, 054310 (2023)

# What I set out to do: refit USDB with a fast emulator and better statistics

Wishlist:

1. Future: fit new interactions in very large model spaces

*Train an emulator for shell model calculations  
(eigenvector continuation)*

Inspired by: S. Yoshida *et al.*, Prog. Theor. Exp. Phys. 2022 053D02

2. Credible uncertainty estimation

*Fit using robust statistical tools: MCMC*

Inspired by: C. Pruitt *et al.*, PRC 107, 014602 (2023)

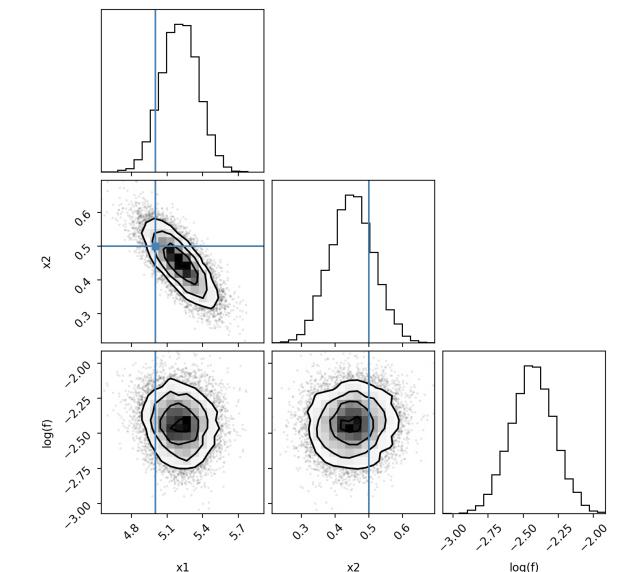

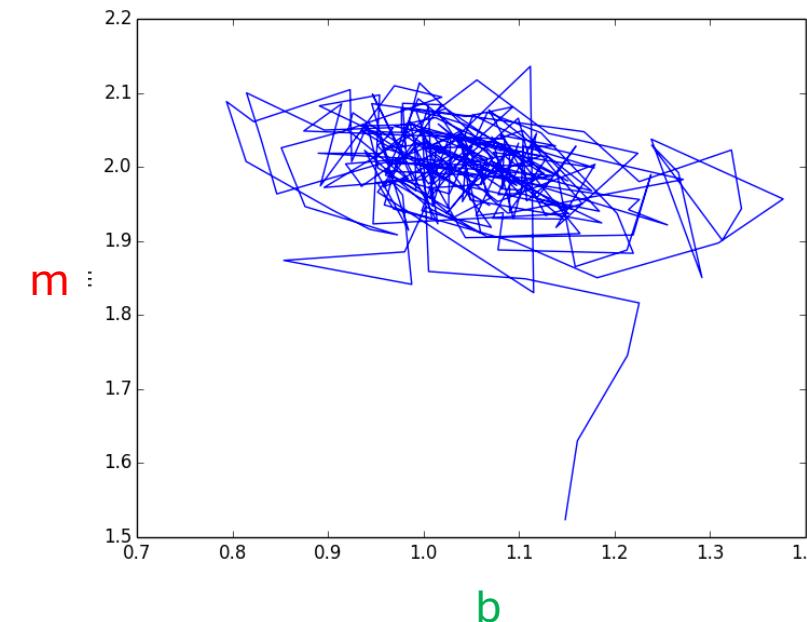

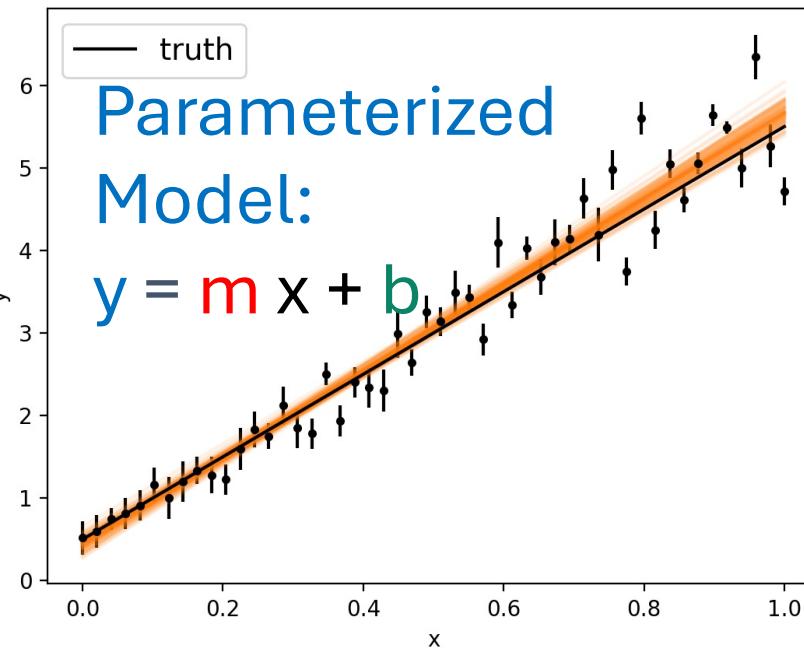

# Ready for Markov Chain Monte Carlo (MCMC)

$\chi^2$ -minimization UQ analysis:

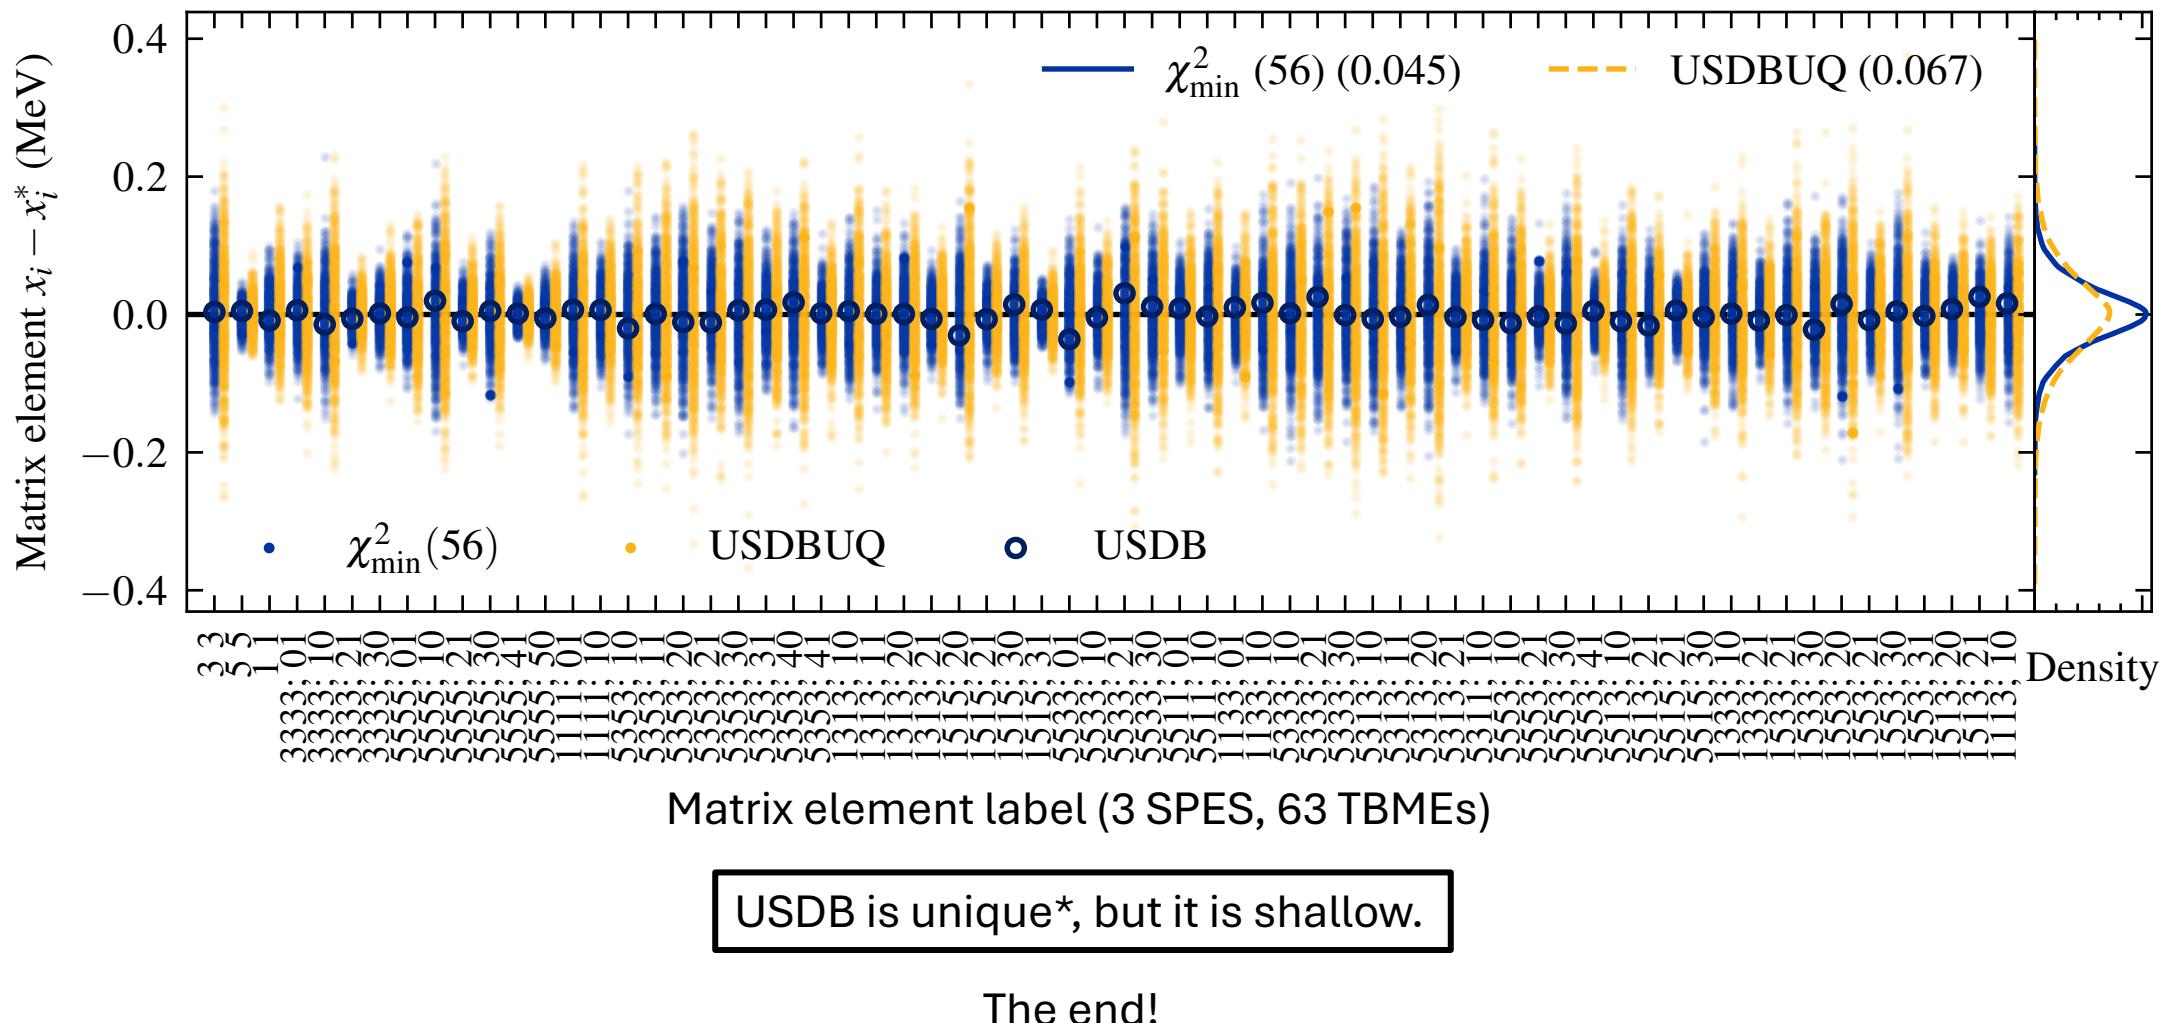

- Uncertainty set by parameter-of-fit:  $\sigma(\text{theory})$
- Analysis assumes linear approximation
- Assumes multivariate normal distribution of parameters

MCMC UQ analysis:

- Uncertainty set by parameter-of-fit:  $\sigma(\text{theory})$
- ~~Analysis assumes linear approximation~~
- ~~Assumes multivariate normal distribution of parameters~~

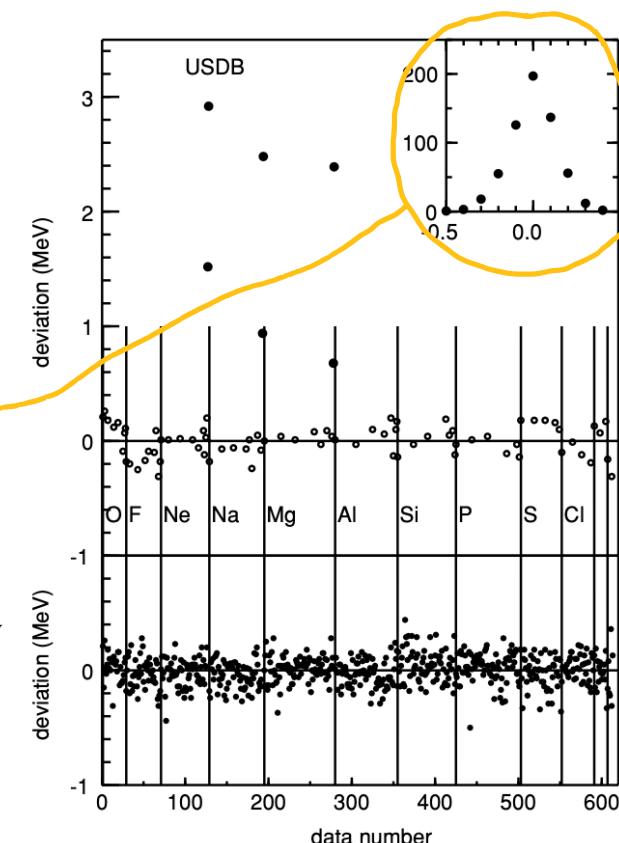

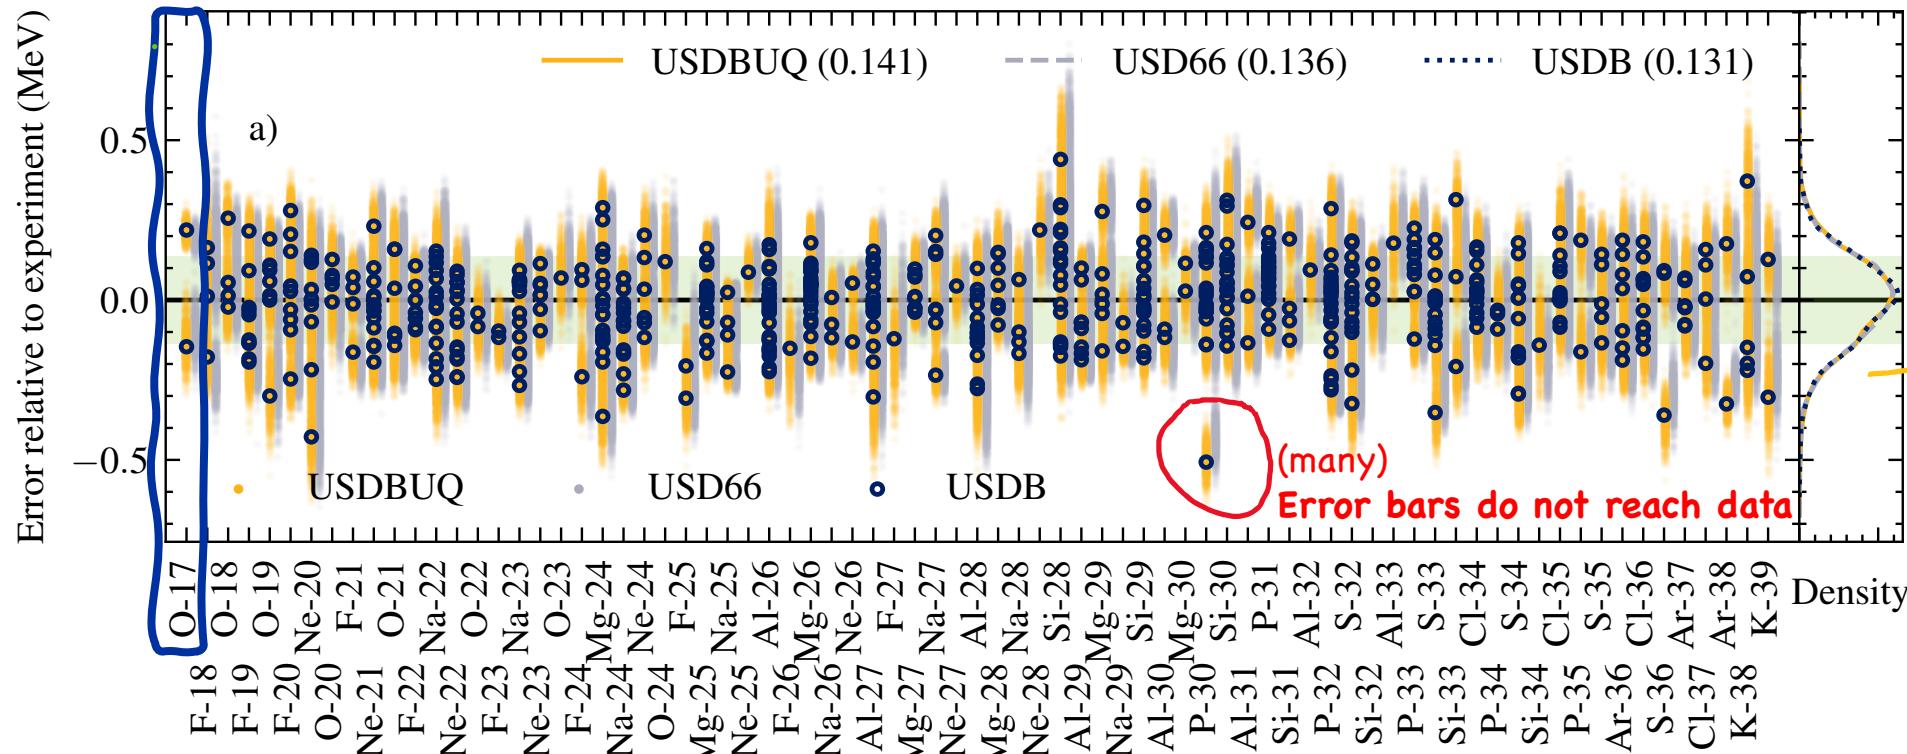

# Introducing USDB with UQ, “USDBUQ”

# USDBUQ: USDB with error bars. Are they credible?

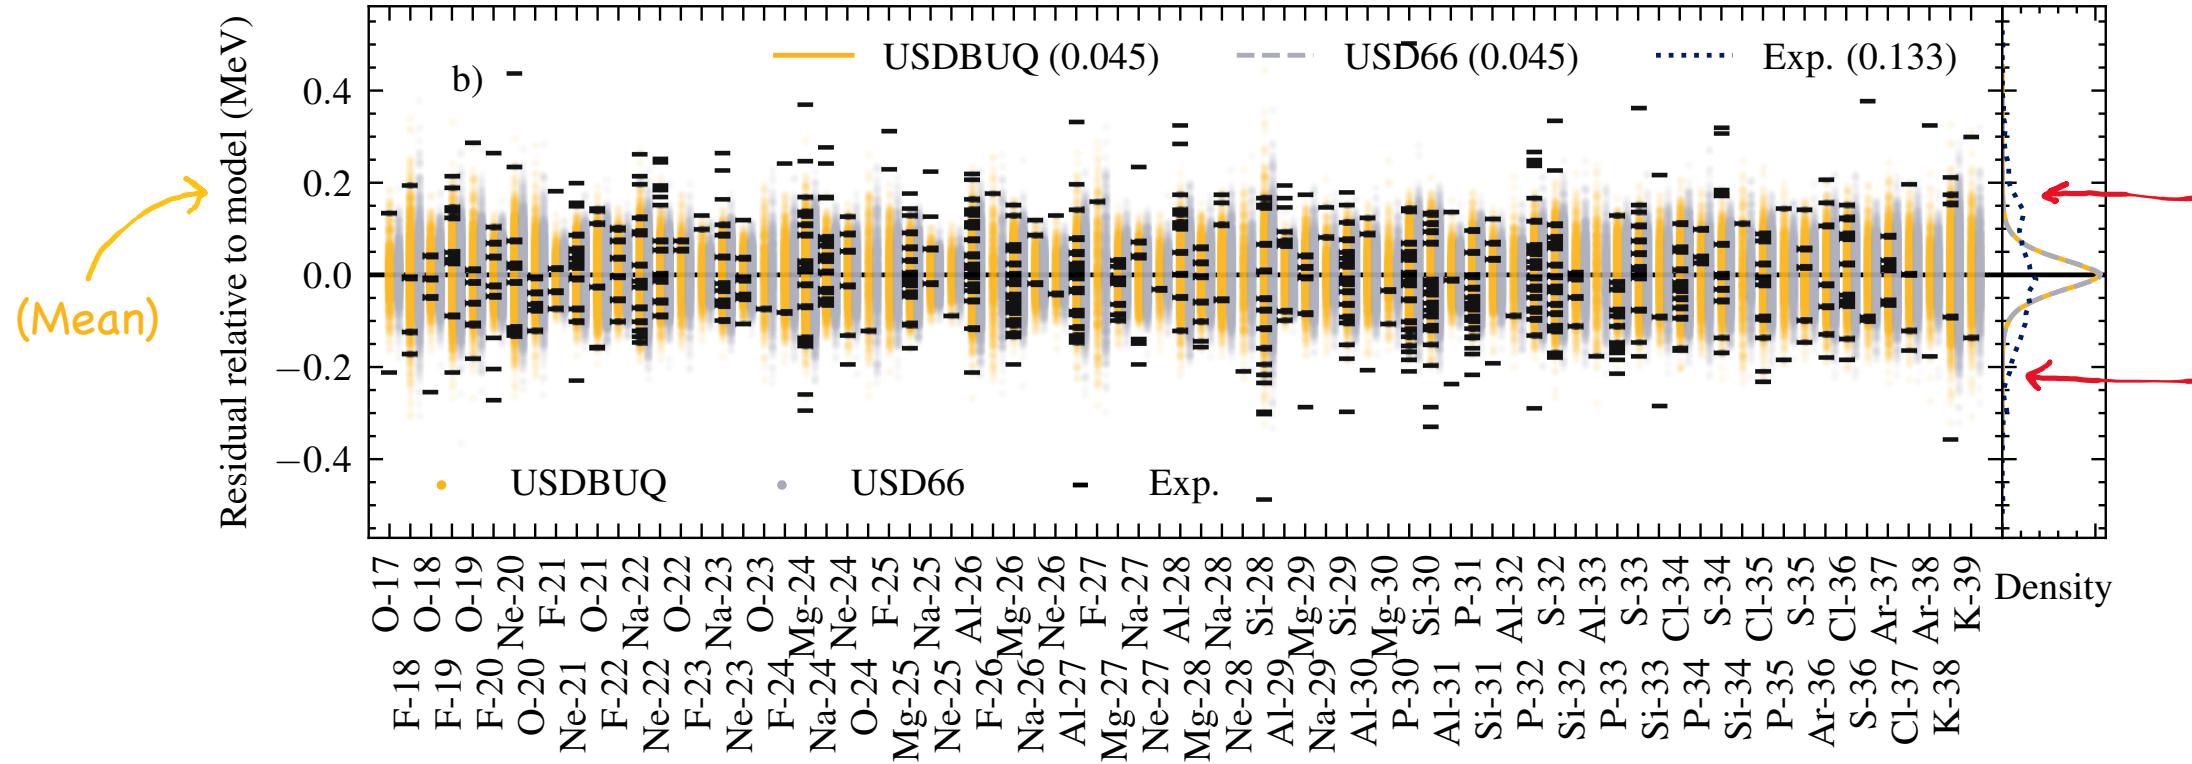

Just like USDB classic, the standard error is  $\sim$ 130-140 keV

But wait, the error bars do not seem to cover the data!

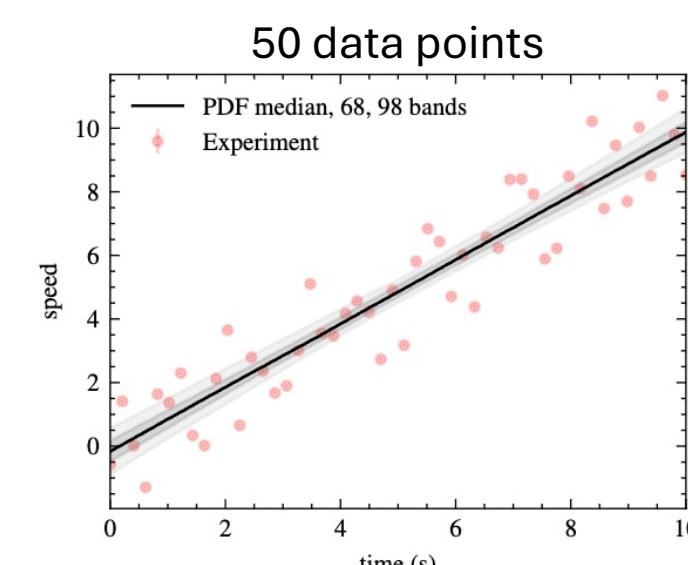

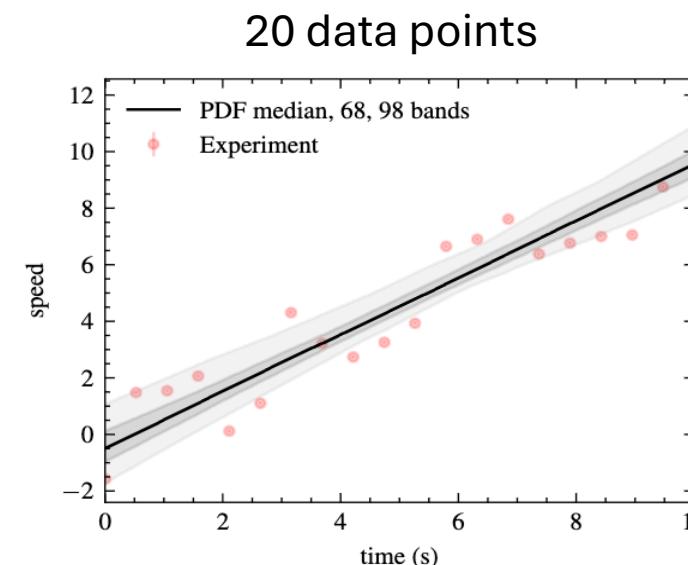

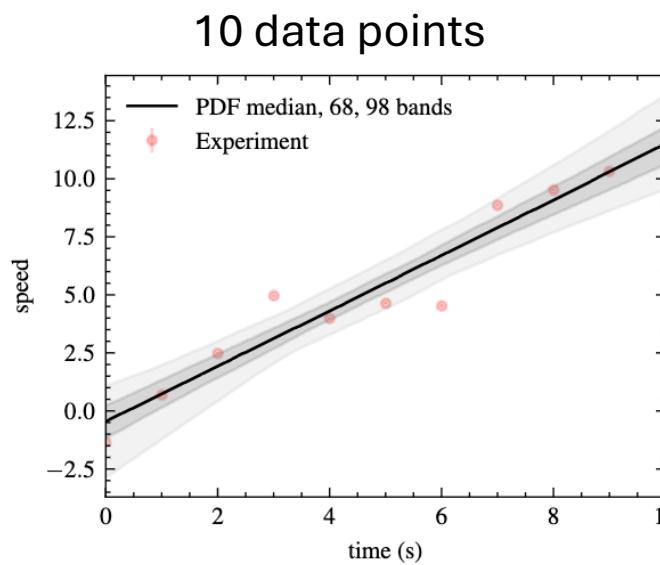

# Let's center the errors on the model:

99% **confidence interval** covers only **40%** of the data

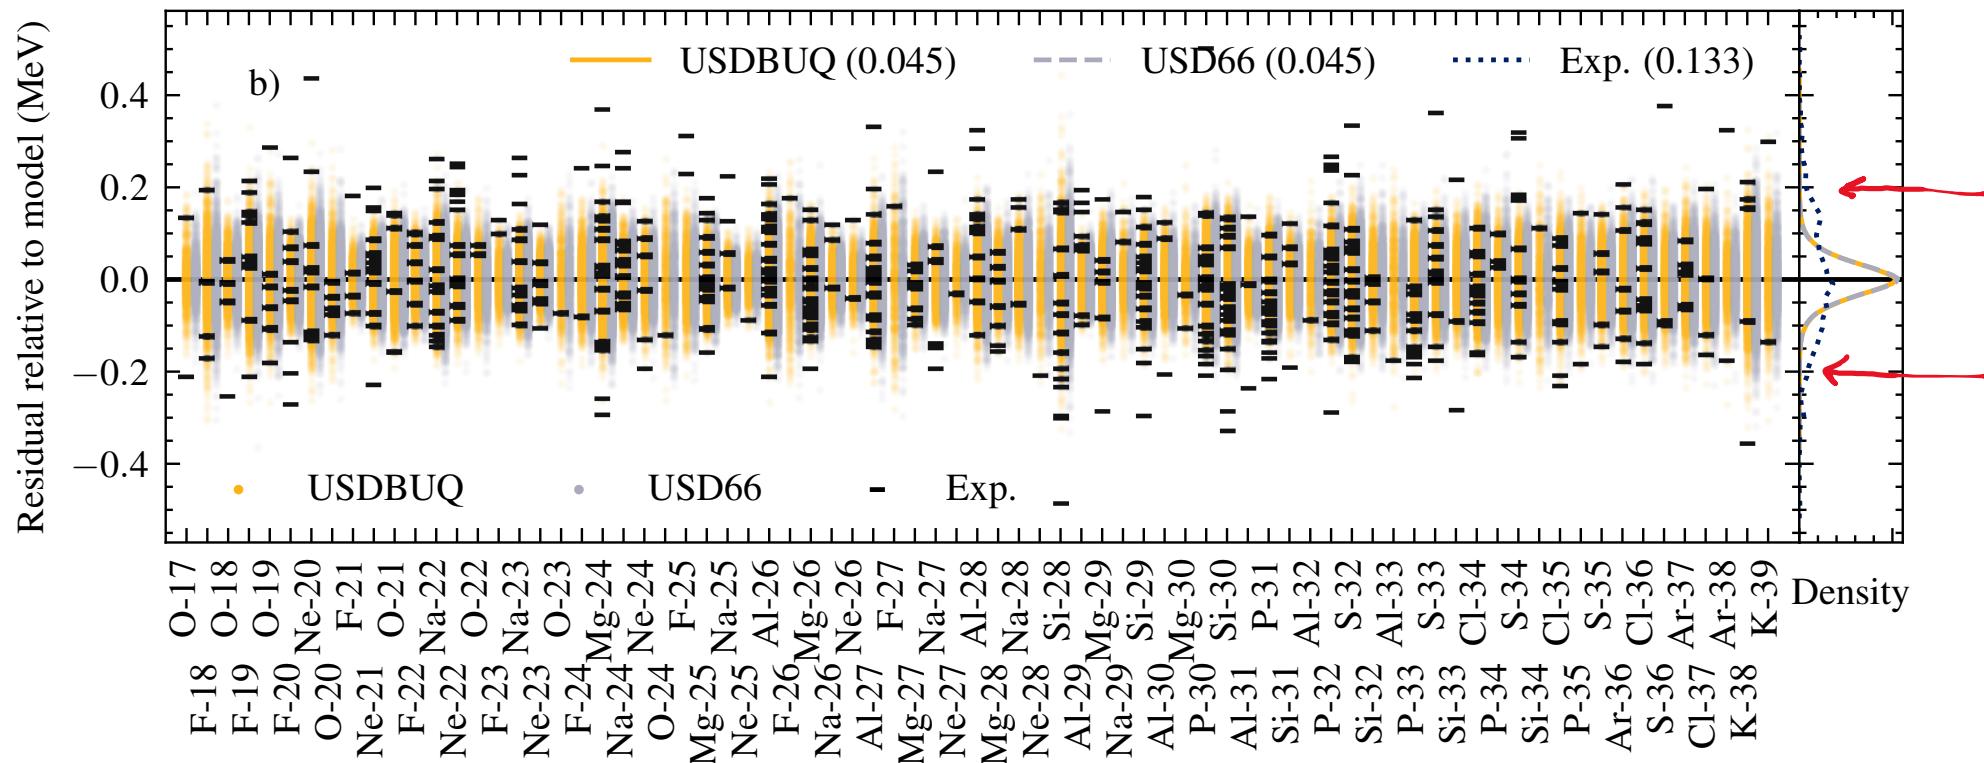

USDBUQ (and previous fits) may be **overconfident**

# With uncorrelated noisy measurements, confidence intervals shrink with number of data

“Noise from flawed measurements are washed out”

# Residual is dominated by *systematic* and *correlated* model defect, NOT noisy measurement!

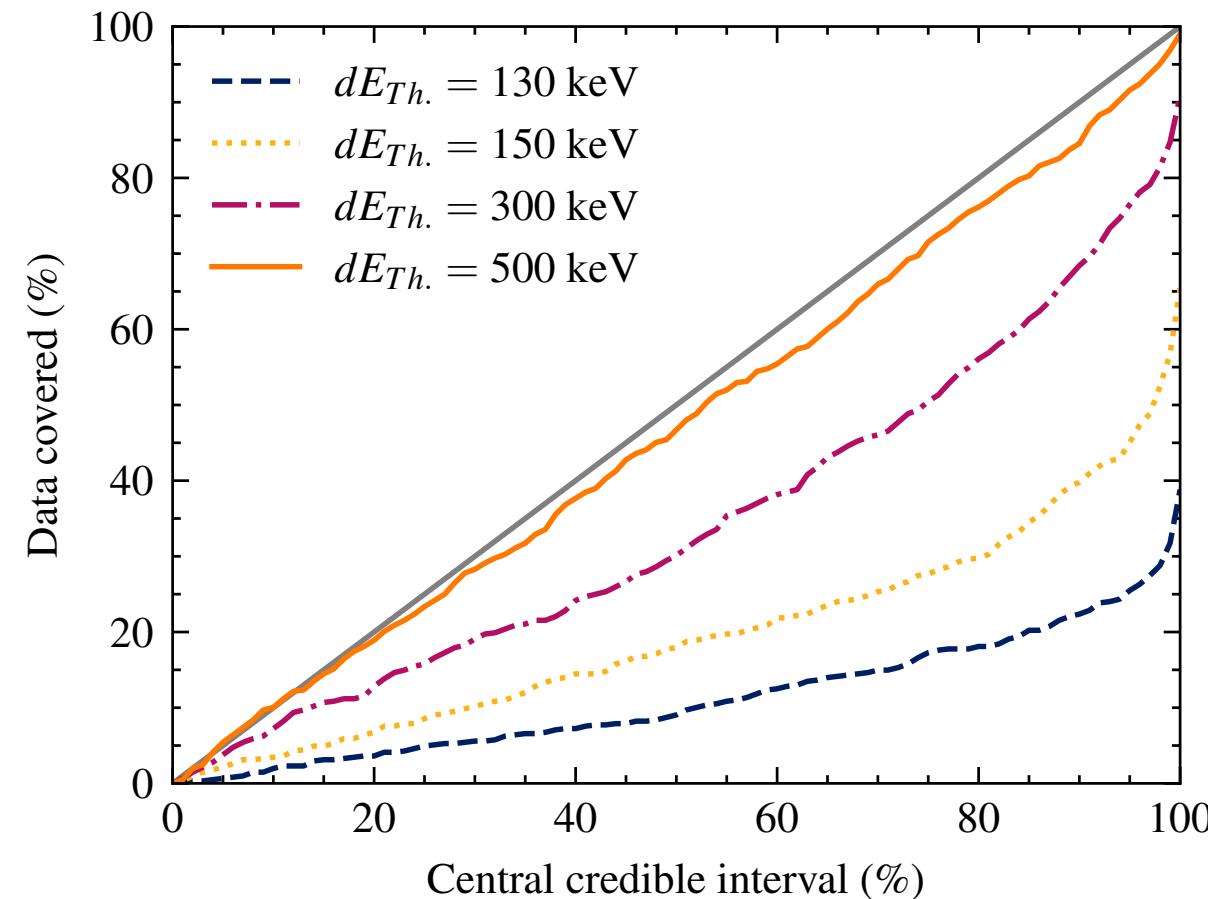

$$\sigma_i^2 = \sigma_i^2(\text{Experiment}) + \sigma_i^2(\text{Theory})$$

a few keV << 130 keV

We do NOT want **confidence intervals** to decrease with # of data

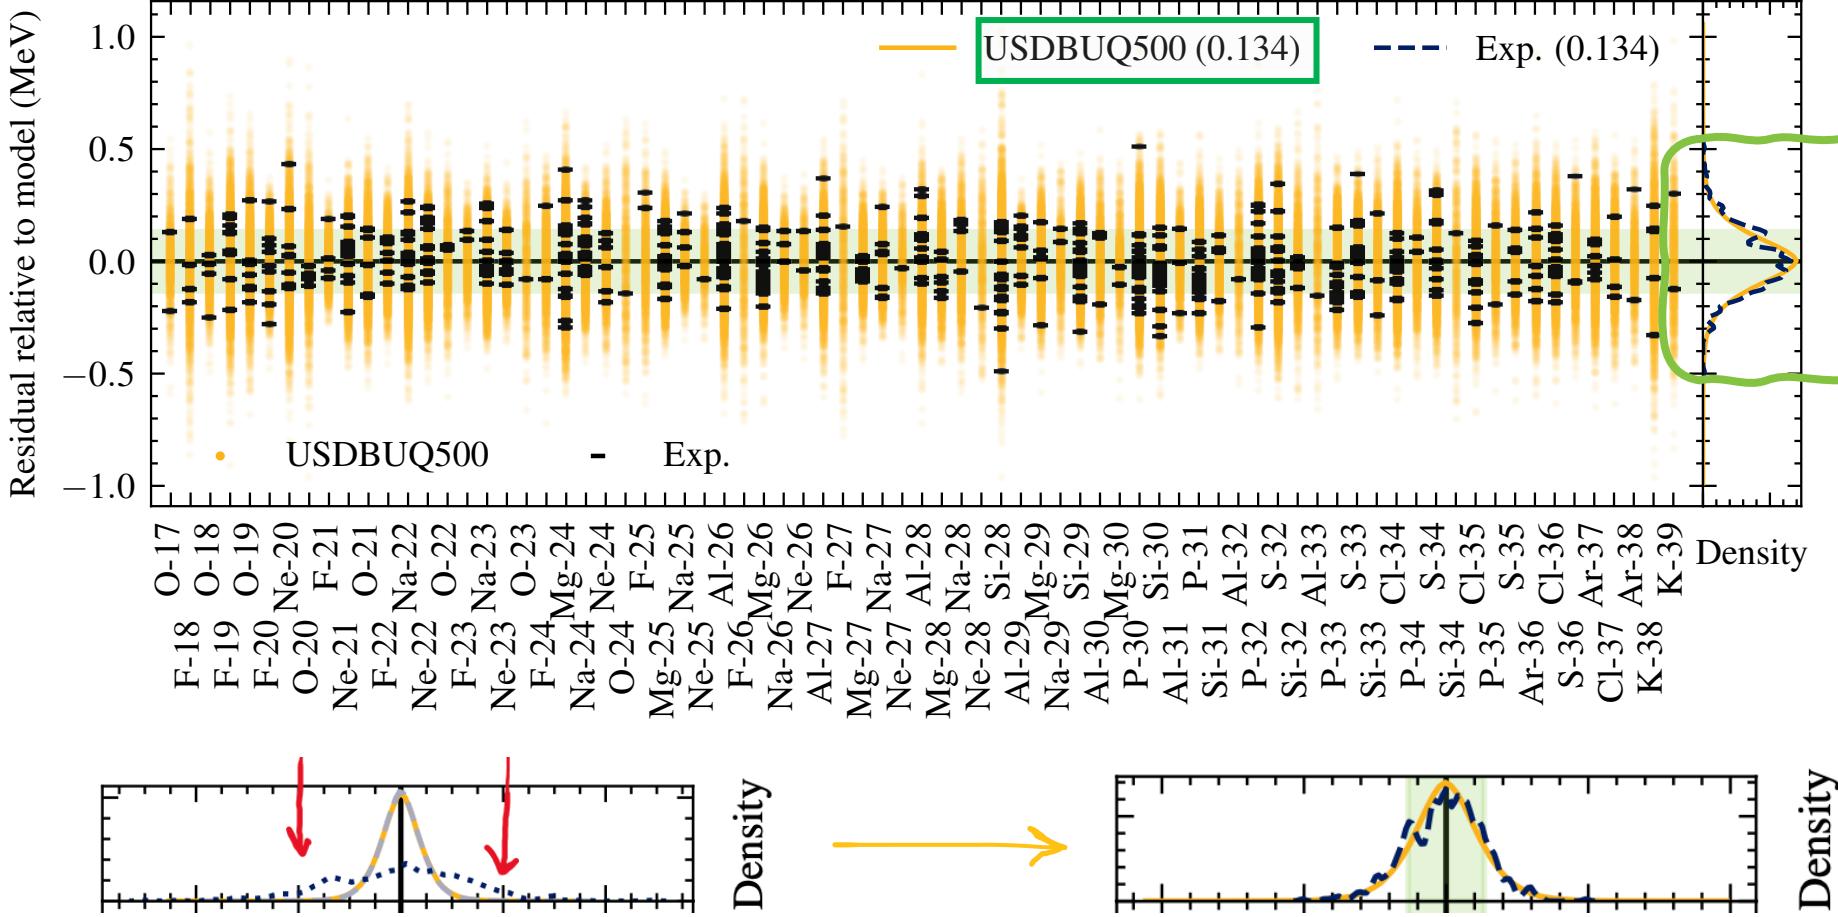

This sets the size of error bars

# Working solution: empirical data coverage test

Does this mean the Shell model uncertainty is 500 keV instead of 130 keV?

# Takeaway: be careful when applying “textbook” statistics to real problems

500 keV is not actual uncertainty  
USDBUQ500 stat sheet  
  
Standard error of random prediction:  
• 190 keV (USDB is 130 keV)  
  
Standard error of averaged prediction:  
• 134 keV  
  
Average half-width of error bar:  
• 134 keV
